(Project Proposal) Exploring Instability

Creating an Instability Matrix

This is the code for creating an instability matrix, using SAEs. Essentially, once we have extracted a specific feature that we think relates to a bias, we want to extract all weights that were responsible for triggering that bias and destabilize them. The instability matrix is a binary matrix that is "1" when a weight is likely responsible, and "0" otherwise.

First, we install necessary libraries, import them, and log onto HuggingFace.

```
# Upgrade pip, setuptools, wheel
!pip install --upgrade pip setuptools wheel

# Install necessary libraries with updated datasets and pyarrow
!pip install pyarrow==15.0.0 datasets==2.19.0 torch transformer_lens sae_lens huggingface_hub
```

Then, we load our models.

We have chosen Gemma-2-2b as our LLM. This is because it is a small, open-source model, making it practical; and it is popular in research papers, making it easier for us to compare our work with others.

https://huggingface.co/google/gemma-2-2b

We have chosen Gemma Scope MLP as our SAE and are focusing on layer 12, as this SAE is pretrained and compatible with Gemma-2-2b, and easily interpretable on Neuronpedia.

https://www.neuronpedia.org/gemma-2-2b/12-gemmascope-mlp-16k/

```
# Load the Gemma model (gemma-2-2b is small, making it practical, and it is popular in research papers)

model = HookedTransformer.from_pretrained(
    "google/gemma-2-2b",
    device=device,
    dtype=torch.bfloat16,
    checkpoint_value=None,
    device_map="auto",
    low_cpu_mem_usage=True
)
```

```

```

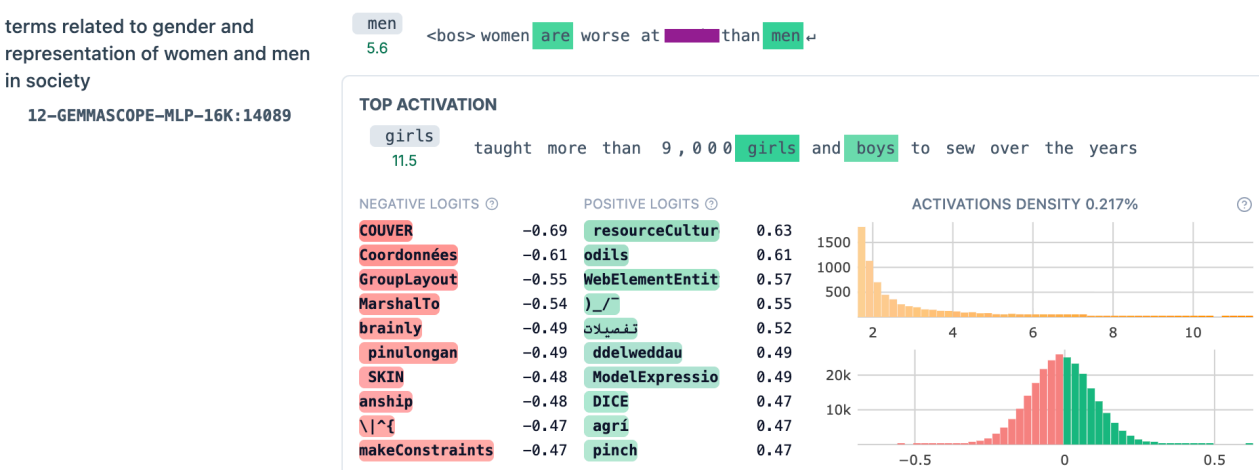
Finding Features Related to Bias

It is hard to know which features of an SAE correspond to what. Typically, we would have to test hypotheses with contrastive datasets, or some other more advanced method. However, Neuronpedia let's us do this easily and quickly.

For example, here is what feature 14809 actually means.

https://www.neuronpedia.org/gemma-2-2b/12-gemmascope-mlp-16k



(Main Project) Training with Instability

Now, we want to train with instability. To do so, we will create a new special model class.

Setup

```
# Install necessary libraries (specific versions of datasets because of loading issue, pyarrow because comp
!pip install pyarrow==15.0.0 datasets==2.19.0 torch transformer_lens sae_lens huggingface_hub bitsandbytes
```

Show hidden output

```
import torch
from transformer_lens import HookedTransformer
from sae_lens import SAE
from torch.optim import Adam
from torch.optim import AdamW
from transformers import AutoModelForCausalLM
from huggingface_hub import notebook_login
from datasets import load_dataset
from transformers import AutoTokenizer
from torch.utils.data import DataLoader
from transformers import DataCollatorWithPadding
import bitsandbytes as bnb
from peft import LoraConfig, get_peft_model, PeftModel
from transformers import BitsAndBytesConfig
from tqdm.notebook import tqdm
import os
import gc
```

```
# Log onto HuggingFace (model and dataset access)
from huggingface_hub import notebook_login
notebook_login()
```

```
# Specify device as GPU if possible
device = "cuda" if torch.cuda.is_available() else "cpu"
```

```
# Mount Google drive so we can save the trained model(s)
# (adding this here as this is a crucial step and easy to miss, for some reason
# no error raised)
from google.colab import drive
drive.mount('/content/drive')
```

```
Drive already mounted at /content/drive; to attempt to forcibly remount, call drive.mount("/content/drive",
```

InstabilityGemma ("new" model that trains with instability)

We define a new InstabilityGemma PyTorch class, with all the necessary hyperparameters (the target layer we think stores meaningful representations that would be useful to modify, the exp decay factor to control how long instability lasts, the instability multiplier to control how much instability is induced).

We use BitsAndBytes for quantization (4bits as we are very low on memory here) and also use LoRA (again, low memory).

The instability matrix is calculated as before and the destabilization is simply a translation of the equations on our overleaf.

```
class InstabilityGemma(torch.nn.Module):
  def __init__(self, sae=None, target_layer=12, lambda_=1.0, multiplier=1.005, saved_model=None):
    """ Initialize an InstabilityGemma model based on  "google/gemma-2-2b-it"

    Here, we actually want to initialize our model parameters to match
    the base Gemma model. Then, we want to set up a few more attributes to help
    with destabilization.
    """
    super().__init__()

    # Set up BitsAndBytes config
    bnb_config = BitsAndBytesConfig(
        load_in_4bit=True,
        bnb_4bit_use_double_quant=True,
        bnb_4bit_quant_type="nf4",
        bnb_4bit_compute_dtype=torch.bfloat16
    )
```

```
    # Load the gemma model with the 4 bit config
    gemma_model = AutoModelForCausalLM.from_pretrained(
        "google/gemma-2-2b-it",
        quantization_config=bnb_config,
        device_map="auto"
    )

    # Enable gradient checkpointing for memory
    # gemma_model.gradient_checkpointing_enable()
    # gemma_model.enable_input_require_grads()

    # We will target a downlayer as these map representations back down to the model
    # But perhaps we could also target the uplayer?
    # For now, set up LoRA adapters for the first
    if saved_model is None:
      lora_config = LoraConfig(
          r=16,
          lora_alpha=16,
          target_modules=["up_proj"],
          task_type="CAUSAL_LM"
      )
      # Load our gemma model and initialize the SAE on device
      self.gemma = get_peft_model(gemma_model, lora_config)
    else:
      # Use previous model with prev LoRA
      self.gemma = PeftModel.from_pretrained(gemma_model, saved_model, is_trainable=True)

    """
    # reset destabilization matrix each time to prevent compounding
    # Note: we should NOT reset when instability is low as then we can allow
    # some repeated weight change multiplication without fear of collapse
    self.destabilization_matrix.fill_(1.0)

    # Update destabilization matrix based on instability matrix
    self.destabilization_matrix[instability_matrix == 1.0] = self.multiplier

    # Apply destabilization
    if self.target_weights.grad is not None:
      # TODO: check this is in fact element-wise
      self.target_weights.grad *= self.destabilization_matrix

    # Apply decay before next round if instability is high
    # This is only uncommented when instability is low
    #self.destabilization_matrix = torch.clamp(
    #    self.destabilization_matrix * self.decay,
    #    min=1.0
    #)
```

Preparing BBQ for Training & Testing

Now that we have defined the main PyTorch class and methods, we need to deal with the datasets. For simplicity, we just want the model to guess the correct letter for each MCQ question in BBQ, so we define a huggingface conversation template with prompt and answer designed accordingly. The answer label is basically the prompt itself but we ignore all tokens that aren't the answer, as we only want to "grade" the LLM on the MCQ choice.

```
def format_bbq_example(example):
  """ Format BBQ examples
  """
  # Format prompt combining context and question
  prompt = example['context'] + " " + example['question']
  prompt += f" Answer with 'A' for {example['ans0']}, 'B' for {example['ans1']}, 'C' for {example['ans2']}'
  prompt += " Your answer should be one capital letter, and absolutely nothing more."

  # Get the answer
  letter_answers = {0: "A", 1: "B", 2: "C"}
  answer = letter_answers[example['label']]

  # Format conversation for huggingface
  chat = [
        {"role": "user", "content": prompt},
        {"role": "model", "content": answer}
  ]
```

```
  # Apply hf template to tokenizer (keep readable at first) and tokenize
  # We tokenize with length 256, may need to chsnge this if some use more?
  formatted_chat = tokenizer.apply_chat_template(chat, tokenize=False)
  tokens = tokenizer(formatted_chat, padding="max_length", truncation=True, max_length=256, return_tensors=
  tokens = {k: v.squeeze(0) for k, v in tokens.items()}

  input_ids = tokens["input_ids"]
  attention_mask = tokens["attention_mask"]

  # Create the labels (same because the LLM must predict itself)
  labels = input_ids.clone()

  # Ignore all tokens only there for padding
  # Cross Entropy Loss ignore_index value is -100 by default so we just use that
  labels[attention_mask == 0] = -100

  # Calculate prompt length (take prompt, tokenize) and then ignore prompt from loss as well
  # as we only want to calculate loss on the answer
  prompt_chat = [{"role": "user", "content": prompt}]
  prompt_str = tokenizer.apply_chat_template(prompt_chat, tokenize=False, add_generation_prompt=True)
  prompt_length = tokenizer(prompt_str, return_tensors='pt')["input_ids"].shape[1]
  labels[:prompt_length] = -100

  return {
        "input_ids": input_ids,
        "attention_mask": attention_mask,
        "labels": labels
    }
```

```
# Load gender, age part of BBQ
age_dataset = load_dataset("heegyu/bbq", "Age", split="test")
gender_dataset = load_dataset("heegyu/bbq", "Gender_identity", split="test")

# Load tokenizer for model and pad token for same length consistency
tokenizer = AutoTokenizer.from_pretrained("google/gemma-2-2b-it")
tokenizer.pad_token = tokenizer.eos_token
tokenizer.padding_side = "right"
```

Instability Gemma Training Loop

Now that we have the model class and the processed data, we can instantiate the model with the same SAE as before and then prepare the training loop. We will train and save periodicially (GPU limits on Colab), and then continue training from where we left off until complete.

Addressing Gender Bias

```
# Load the SAE to use with the gemma model
sae, sae_config, sparsity = SAE.from_pretrained(
    release="gemma-scope-2b-pt-mlp-canonical",
    sae_id="layer_12/width_16k/canonical",
    device=device
)
```

```
/usr/local/lib/python3.12/dist-packages/sae_lens/saes/sae.py:249: UserWarning:
This SAE has non-empty model_from_pretrained_kwargs.
For optimal performance, load the model like so:
model = HookedSAETransformer.from_pretrained_no_processing(..., **cfg.model_from_pretrained_kwargs)
  warnings.warn(
/tmp/ipykernel_15838/3869731826.py:2: DeprecationWarning: Unpacking SAE objects is deprecated. SAE.from_pre
  sae, sae_config, sparsity = SAE.from_pretrained(
```

Biased SAE Feature 1

```
model = InstabilityGemma(sae=sae, multiplier=1.005)

# Define the optimizer as standard Adam with standard learning rate
optimizer = bnb.optim.AdamW8bit(model.parameters())

# Put the model in training mode
model.train()

# Define feature to adjust with instability
# Note: For now, we are just taking the approach where we go one feature at a time.
#       So we will just train for a few main gender-related or age-related features
#       likely to have bias.
# TODO: change the above after implementing support for a list of features

# 14809 = terms related to gender and representation of men and women in society
target_feature = 14809

# Go over data 3 times, adjust if very slow
epochs = 1
```

```
Loading checkpoint shards: 100%  2/2 [00:35<00:00, 14.96s/it]
```

```
# Initialize DataCollatorWithPadding
data_collator = DataCollatorWithPadding(tokenizer=tokenizer, padding="max_length", max_length=256)

# Set batch size (small for saving)
batch_size = 1
grad_accum = 4

# Pass the collator to the DataLoader
train_dataloader = DataLoader(
    gender_train_data,
    batch_size=batch_size,
    shuffle=True,
    collate_fn=data_collator
)
```

```
# For memor saving
os.environ["PYTORCH_CUDA_ALLOC_CONF"] = "expandable_segments:True"
```

```
# Mount Google drive so we can save the trained model
from google.colab import drive
drive.mount('/content/drive')
```

```
Drive already mounted at /content/drive; to attempt to forcibly remount, call drive.mount("/content/drive",
```

```
save_dir_root = "/content/drive/MyDrive/gender_1.005_gemma_bbq_checkpoints_v2"
```

```
# Actual training loop

for epoch in range(epochs):
  loop = tqdm(train_dataloader, total=len(train_dataloader), desc=f"Epoch {epoch + 1} of {epochs}", positi
  for step, batch in enumerate(loop):
    if step > 100:
      break
    # Move all to GPU device
    input_ids = batch['input_ids'].to(device)
    attention_mask = batch['attention_mask'].to(device)
    labels = batch['labels'].to(device)

    # Clean gradients
    optimizer.zero_grad()

    # Forward pass
    outputs = model(
        input_ids=input_ids,
        attention_mask=attention_mask,
        labels=labels
    )

    # Compute loss
    loss = outputs.loss
    loop.set_postfix(loss=f"{loss.item():.4f}")

    # Backward pass FIRST
    loss.backward(retain_graph=True)

    # THEN compute instability (target_weights.grad now exists)
    instability_matrix = model.compute_instability_matrix(target_feature)

    # Clip, then destabilize
    torch.nn.utils.clip_grad_norm_(model.parameters(), max_norm=1.0)
    model.destabilize(instability_matrix)

    optimizer.step()

    # Save model every 100 steps
    if step % 100 == 0:
```

```
        save_dir = os.path.join(save_dir_root, "latest-checkpoint")
        model.gemma.save_pretrained(save_dir)
        tokenizer.save_pretrained(save_dir)

    # Clean actives from hook
    model.target_layer_outputs = None

    # Empty cache, collect garbage for memory
    torch.cuda.empty_cache()
    gc.collect()
```

Epoch 1 of 1: 2% 101/4254 [03:18<2:34:09, 2.23s/it, loss=6.8451]

Since the model will almost definitely crash after some time due to Google colab's GPU limits, we need code to retrieve the latest version and resume training with either (a) a new account or (b) the same account but refreshed. This means we should also share the gemma_bbq_checkpoints folder to all accounts we plan to use.

```
# TODO: write code for continuing where it leaves off if it actually crashes before completion of an epoch
```

After this is done, we likely want to destabilize a few other SAE features for gender (maybe less epochs if they are less central), and then repeat the same for age.

For gender, the Neuronpedia relevent contenders (may encode gender bias) include:

**14809: **"terms related to gender and representation of women and men in society" (already processed above)
https://www.neuronpedia.org/gemma-2-2b/12-gemmascope-mlp-16k/14089

3889: "references to personal identity and relationships, particularly involving female subjects"
https://www.neuronpedia.org/gemma-2-2b/12-gemmascope-mlp-16k/3889

5473: "references to individuals, particularly focusing on their roles and relationships in various contexts "
https://www.neuronpedia.org/gemma-2-2b/12-gemmascope-mlp-16k/5743

Biased SAE Feature 2

```
# Reconstruct model from saved file and continue debiasing on different neuron

prev_save_dir = "/content/drive/MyDrive/gemma_bbq_checkpoints/latest-checkpoint"

# Get tokenizer
tokenizer = AutoTokenizer.from_pretrained(prev_save_dir)

# Get model
model = InstabilityGemma(sae, multiplier=1.025)
```

Loading checkpoint shards: 100% 2/2 [00:43<00:00, 18.21s/it]

```
optimizer = bnb.optim.AdamW8bit(model.parameters())
model.train()
epochs = 1
target_feature = 3889

# Initialize DataCollatorWithPadding
data_collator = DataCollatorWithPadding(tokenizer=tokenizer, padding="max_length", max_length=256)

# Set batch size (small for saving)
batch_size = 1
grad_accum = 4

# Pass the collator to the DataLoader
train_dataloader = DataLoader(
    gender_train_data,
    batch_size=batch_size,
```

```
        shuffle=True,
        collate_fn=data_collator
    )

    # For memor saving
    os.environ["PYTORCH_CUDA_ALLOC_CONF"] = "expandable_segments:True"
```

```
    # Actual training loop

Zero Instability Age Bias Reduction

↳ 12 cells hidden

Measuring and Comparing Performance Across InstabilityGemma Variations

Now that we have trained different versions of the InstabilityGemma model, we want to use the test data for gender and age to see how much we are able to improve / reduce biased representations in each case. A separate codebook will test retention of basic knowledge for each case.

First, we will need to reconstruct each of our models from the saved files of the `latest-checkpoint`s.

```
# TODO: define paths based on whose Google Drive everything is saved in
# TODO: then, load the models from those paths.
```

```
import pandas as pd
```

```
def format_prompt(example):
    prompt = example["context"] + "\n\n" + example["question"] + "\n"
    for idx, choice in enumerate([example["ans0"], example["ans1"], example["ans2"]]):
        prompt += f"{chr(65 + idx)}. {choice}\n"
    prompt += "\nAnswer the above question with one of the provided choices."
    prompt += "\nAnswer:"
    return prompt
```

```
import re

def parse_letter(generated_text):
    """First standalone A/B/C — avoids 'A' in ANSWER etc."""
    if not generated_text:
        return None
    text = generated_text.strip().upper()
    m = re.search(r"\b([ABC])\b", text)
    if m:
```

```
        return {"A": 0, "B": 1, "C": 2}[m.group(1)]
    line0 = text.splitlines()[0].strip()
    if line0 and line0[0] in "ABC":
        return {"A": 0, "B": 1, "C": 2}[line0[0]]
    return None

```

```
Accuracy: 68.0%
```

Somehow (perhaps because we are encouraging very specific weights to change), the accuracy retention is better on the Labile state model than the non-labile state model?? Whatever the reason, this is a promising result.

To summarize the retention results we see, here is a quick list:

Non-Labile Gender: 69.86%

Non-Labile Age: 68.00%

Labile Gender: 67.80%

Labile Age: 52.00%

To present these visually, we create a heatmap (essentially copying what we did before to create accuracy heatmaps).

```
from google.colab import drive
import pandas as pd
import numpy as np
import matplotlib.pyplot as plt
import seaborn as sns

heatmap_data = {
    'No Training': [72, 67.81],
    'Non-Labile': [68,  69.86],
    'Labile': [52, 67.80],
```

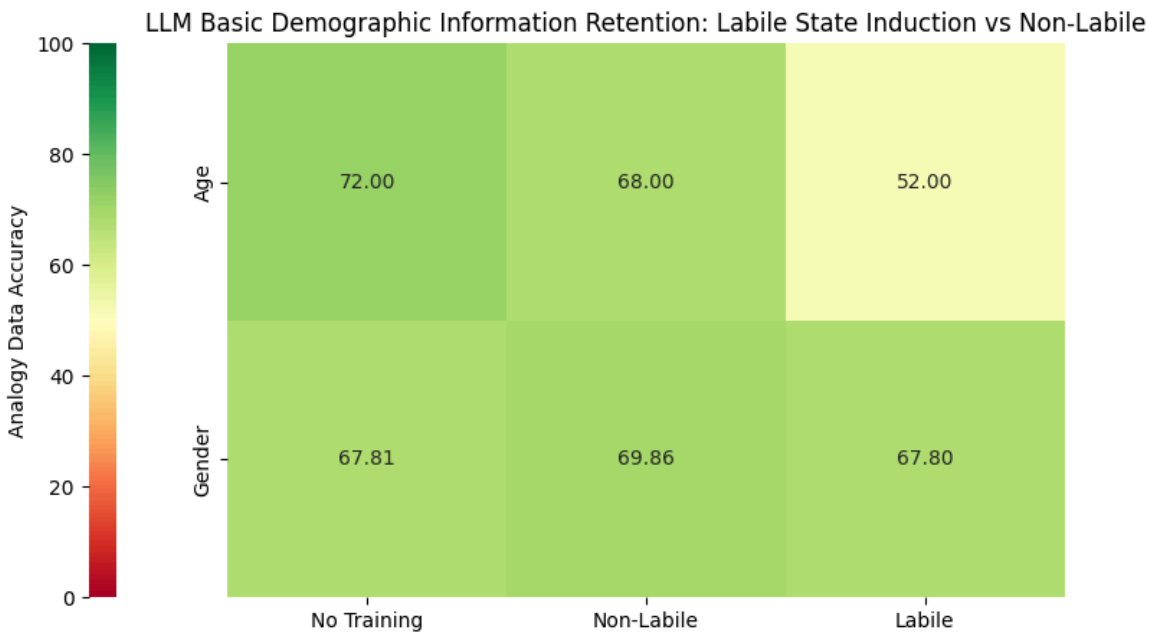
```
}

df = pd.DataFrame(heatmap_data, index=['Age', 'Gender'])

plt.figure(figsize=(10, 5))

# Heatmap from Red (for 0%) to Green (for 100%), 2f accuracy displays
acc_cmap = plt.get_cmap('RdYlGn')
acc_cmap.set_bad('lightgrey')
sns.heatmap(df, annot=True, cbar_kws={'label': 'Analogy Data Accuracy', 'location': 'left'}, cmap=acc_cmap,

# Commenting out title because honestly the overleaf caption looks better and is enoguh
plt.title("LLM Basic Demographic Information Retention: Labile State Induction vs Non-Labile")
plt.show()
```



To strengthen our narrative, it is best to also add results about how the original gemma model performs (the one that is not trained at all).

```
model = InstabilityGemma()
```

```
